

# Adaptability and Fault Tolerance

*Rogério de Lemos*  
University of Kent, UK

- ◆ Context: self-\* and dependability;
- ◆ Focus: adaptability and fault tolerance;
- ◆ State of the art;
- ◆ Conclusions;

# *Self-\* and Dependability*

- ◆ Dependability:
  - ◆ the ability to deliver service that can justifiably be trusted;
  
- ◆ Self-\* properties of systems:
  - ◆ the support for autonomy;
  - ◆ self-adaptable, self-managing, self-optimising, self-healing, self-repairing, self-configuring, etc.
  
- ◆ Adaptability:
  - ◆ the ability of a system of accommodating changes while providing its specified services;
    - ◆ run-time changes;

**Dependability** - the ability to avoid service failures that are more frequent and more severe than is acceptable;

- ◆ **threats** - undesired, but in principle expected circumstances:
  - ◆ faults, errors and failures;
- ◆ **attributes** - properties of the system:
  - ◆ reliability, availability, integrity, confidentiality, and safety;
- ◆ **technologies** - methods and techniques for providing and reach confidence on ability to attain dependability:
  - ◆ rigorous design, validation & verification, fault tolerance, and system evaluation;

# Dependability - Threats

(Yves Deswarte & David Powell)

adjudged or hypothesized cause of an error

that part of system state which may lead to a failure

occurs when delivered service deviates from implementing the system function

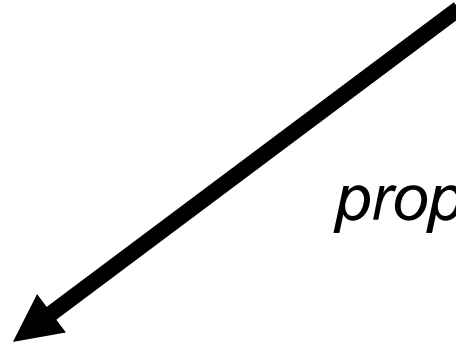

**Error**

activation

propagation

**Failure**

causation

**Fault**

activation

**Error**

# *Adaptability - Initiators*

- ◆ **Changes:**
  - ◆ the act, process, or result of altering or modifying;
  - ◆ internal changes:
    - ◆ component failures, overload of resources, etc.
  - ◆ external changes:
    - ◆ environmental, requirements, etc.
  
- ◆ There is no fundamental chain of adaptability initiators;

## *Threats and Initiators*

- ◆ Changes correspond to events (faults):
  - ◆ changes can be dormant if not activated;
- ◆ What is the consequence of change (errors)?
  - ◆ what would be the equivalent to error free and erroneous states?
  - ◆ these states are created when changes are activated and can remain latent until detected;
- ◆ What is the equivalent of failure?
  - ◆ unsuccessful adaptation?
  - ◆ the system might continue to provide its services, but ignoring the change;

**Fault avoidance:** build a system with no faults:

- ◆ rigorous design - fault prevention;
  - ◆ formal and rigorous notations, processes, adapters, etc.
- ◆ verification & validation - fault removal;
  - ◆ model checking, fault injection, testing, simulation, etc.

**Fault acceptance:** impossible to rid the system of faults:

- ◆ fault tolerance;
- ◆ system evaluation - fault forecasting;
  - ◆ empirical approaches, Markov models, etc.

**Fault tolerance** aims at avoiding the failure of the system:

◆ **error detection:**

- ◆ detects the presence of errors;

◆ **recovery:**

- ◆ transforms a system state that contains errors or faults into a error free state, or faults that can be re-activated;
  - ◆ error handling:
    - ◆ eliminates errors from the system state;
  - ◆ fault handling:
    - ◆ prevents faults from being activated again;
    - ◆ diagnosis, isolation and reconfiguration;

# Fault Tolerance

(Yves Deswarte & David Powell)

adjudged or hypothesized cause of an error

that part of system state which may lead to a failure

**Fault**

**Fault Handling**

Diagnosis, Isolation, Reconfiguration, Reinitialization

occurs when delivered service deviates from implementing the system function

**Error**

**Error Detection**

**Error Handling**

Rollback, Rollforward, Compensation

**Failure**

## *System Structure*

Fault tolerance is about system structuring;

- ◆ structure is what enables the system to generate the behaviour;
- ◆ determines how effectively this structuring can be used to provide means of **error confinement**;
  - ◆ avoid the propagation of errors;
  - ◆ what interactions can exist and at what rate;
- ◆ it is not restricted to system architecture;

**Structural flexibility the basis for adaptation;**

## *Fault Assumptions*

Faults are undesirable, though expected circumstances:

- ◆ systems can fail in many different ways;

In the design of fault-tolerant systems, it is essential to define assumptions:

- ◆ **nature** of faults - dictates the type of redundancy that must be implemented:
  - ◆ space or time;
  - ◆ replication or diversification;
- ◆ **rate** of faults - influences the amount of redundancy needed to attain a given dependability;

## *Fault Assumptions*

How a component behaves when it fails:

- ◆ crash fault being the simplest and most restrictive (or well-defined) type;
- ◆ Byzantine being the least restrictive;

The different types of changes needs to be classified;

- ◆ behavioural assumptions;

## **Adaptive fault tolerance**

- ◆ property that enables a system to maintain and improve fault tolerance by adapting to changes in environment and policy;
  - ◆ monitor the system;
  - ◆ reconfigure the application when its configuration of it is not appropriate for the dependability requirements;
- ◆ distributed systems:
  - ◆ different layers:
    - ◆ middleware / fault tolerance /adaptation;
  - ◆ consensus problem;

- ◆ AQUA - CORBA based operating system;
  - ◆ dynamic replication of objects;
  - ◆ Proteus:
    - ◆ dynamic fault tolerance through adaptive reconfiguration;
    - ◆ allows to specify the degree of dependability at the application level;

- ◆ Chameleon - adaptive infrastructure;
  - ◆ allows different levels of availability requirements;
  - ◆ explicit representation of adaptive policies;
  - ◆ provides dependability through the use of ARMORs (Adaptive, Reconfigurable, and Mobile Objects for Reliability):
    - ◆ managers for monitoring and recovering resources;
    - ◆ daemons for providing communication;
    - ◆ common ARMORs for providing application-required dependability;
  - ◆ enables multiple fault tolerance strategies to co-exist;

## Architectural fault tolerance

- ◆ Error detection and recovery;
  - ◆ techniques based on exception-handling;
    - ◆ application dependent;
    - ◆ iC2C and iFTE;
- ◆ Fault handling
  - ◆ system reconfiguration;
    - ◆ replacement of components, connectors and configurations;
  - ◆ dynamic reconfiguration;

## **Bio-inspired computing and statistical methods:**

- ◆ data-oriented approaches
  - ◆ data mining large quantities of observations for identifying patterns;
- ◆ anomaly (fault and intrusion) detection;
  - ◆ neural networks, genetic algorithms, etc.;
  - ◆ adaptive error detection using artificial immune systems:
    - ◆ problem: how to learn from rare events!
- ◆ statistical learning techniques (SLT) applied to system recovery;

## *Conclusions*

- ◆ Changes are like faults, though:
  - ◆ they might be desired/undesired and expected/unexpected;
- ◆ Classification of the types of changes:
  - ◆ otherwise becomes application dependent;
    - ◆ e.g., exception handling for the support of fault tolerance;
- ◆ How system structuring affects adaptability?
  - ◆ is software that flexible for supporting run-time change?
    - ◆ impact of design-time change;
  - ◆ to scope the impact of change;
    - ◆ confinement of the consequence of change;

### Dependability and adaptability:

- ◆ the ability to deliver service:
  - ◆ D: rigorous design and **fault tolerance**;
  - ◆ A: rigour in the specification/reasoning about adaptability;
  - ◆ A: most work has focused on system reconfiguration;
- ◆ confidence on that ability:
  - ◆ D: V&V and system evaluation;
  - ◆ A: very little has been done here;
    - ◆ adaptability vs. predictability;
